

Insights & Conclusion

The dashboard provides an overview of key academic, financial, and lifestyle factors that may influence student **mental health**. The analysis shows that Academic Pressure Level 3 has the highest number of students (125), suggesting that moderate academic pressure is commonly experienced within the population. Similarly, financial stress is distributed across all categories, with Financial Stress Level 1 recording the highest student count (110), indicating that financial concerns affect students at varying intensities rather than being limited to highly stressed individuals.

Study satisfaction appears relatively positive, with Study Satisfaction Level 4 having the largest number of students (116), while lower satisfaction levels are less frequent. Sleep duration is evenly distributed, with slightly more students reporting 7–8 hours or more than 8 hours of sleep (128 each), highlighting diverse sleep habits among students. Additionally, the study-hours analysis indicates that student participation generally increases with study duration, peaking at 10 study hours before declining, suggesting that study behaviour varies considerably across the population.

Overall, the findings emphasize that student mental health is influenced by multiple interconnected factors rather than a single variable. Academic demands, financial wellbeing, lifestyle habits, and personal satisfaction collectively contribute to the student experience. This project demonstrates how SQL and Tableau can be combined to transform raw educational data into meaningful insights that support evidence-based decision-making and help educational institutions identify trends, prioritize student wellbeing initiatives, and develop targeted mental health support strategies.
